AT | AUTOMATIZACIONES TORRES

NINE CASES / THE COMPLETE WORKFLOW

Functional systems, end to end.

Six working demonstrations, two team products and one documented proposal. Each case retains its actual status.

Jair Alejandro Peinado Otero

Discovery, business analysis and scope

WORKFLOWS

01 Document packets ready for review
02 Order changes with clear approval
03 Inventory availability and reservation controls
04 From equipment intake to service review
05 Receipts and supporting records to reconcile
06 Commercial follow-up with context
07 Mining operations and finance system design
08 An internal commercial operations system
09 Case intake with a private review record

Jair coordinates discovery, analysis and scope. The Automatizaciones Torres team delivers implementation. The demonstrations use fictional data; improvement would be tested against an agreed operational baseline.

WORKING DEMONSTRATION - FICTIONAL DATA

THE PROBLEM

A working team demonstration built with fictional data. A supporting document arrives, but its reporting period does not match the request. The file is present. The decision still needs context.

WORKFLOW AND OUTPUT

The workflow brings together the expected period, the document period and the attachment. Its rules distinguish invalid data from a genuine mismatch and make missing evidence visible. Even when the information matches, the packet becomes ready only after explicit approval.

HUMAN CONTROL AND SCOPE

A responsible person retains the review. The example does not authenticate documents or certify legal compliance. A real pilot would compare assembly time, missing-information questions and reviewer corrections, including the review effort. No measured savings are attributed to this demonstration.

WHAT WE WOULD MEASURE IN A PILOT

Packet preparation time, missing-information questions and reviewer corrections.

WORKING DEMONSTRATION - FICTIONAL DATA

THE PROBLEM

A working demonstration with fictional data. An order can change after a team already has a working reference. This case explores what happens when quantity, finish and approval drift into separate versions.

WORKFLOW AND OUTPUT

The product retains a baseline, compares the requested revision field by field and shows what changed. Invalid quantities block preparation. Detecting a difference is not an approval: the responsible person must confirm the version currently shown before the next instruction can be prepared.

HUMAN CONTROL AND SCOPE

The result is an explainable change with a visible human decision. An implementation would define order identity, permissions, persistent history and the production-system connection. A pilot would examine clarification requests and differences between approved and delivered versions. No achieved reduction is claimed here.

WHAT WE WOULD MEASURE IN A PILOT

Confirmations after changes and differences between the approved and delivered versions.

WORKING DEMONSTRATION – FICTIONAL DATA

AT | AUTOMATIZACIONES TORRES

TEAM DEMONSTRATION / 03

Stock reservations

Known availability.
A retry retains the reservation.

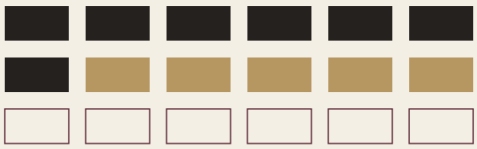

AVAILABLE BEFORE

18 - 7 = 11

A new request for 5 units.
The same confirmed reservation adds none.

FICTIONAL STOCK

18 units in total

■ 7 committed
■ 5 new reservation
□ 6 available

AVAILABLE AFTER 6

Repeating that reservation adds 0 units.

Automatizaciones Torres · Team demonstration · Fictional data

THE PROBLEM

A working team demonstration with fictional data. Before promising units, a team needs to know what exists, what is committed and whether the request has already been handled. Unknown availability and a confirmed zero require different responses.

WORKFLOW AND OUTPUT

The model calculates availability and explains why it accepts or holds a request. It does not create a partial reservation when the balance is insufficient. If the caller explicitly confirms that the same reservation is already included in commitments, it preserves the balance and reports no new reserved units.

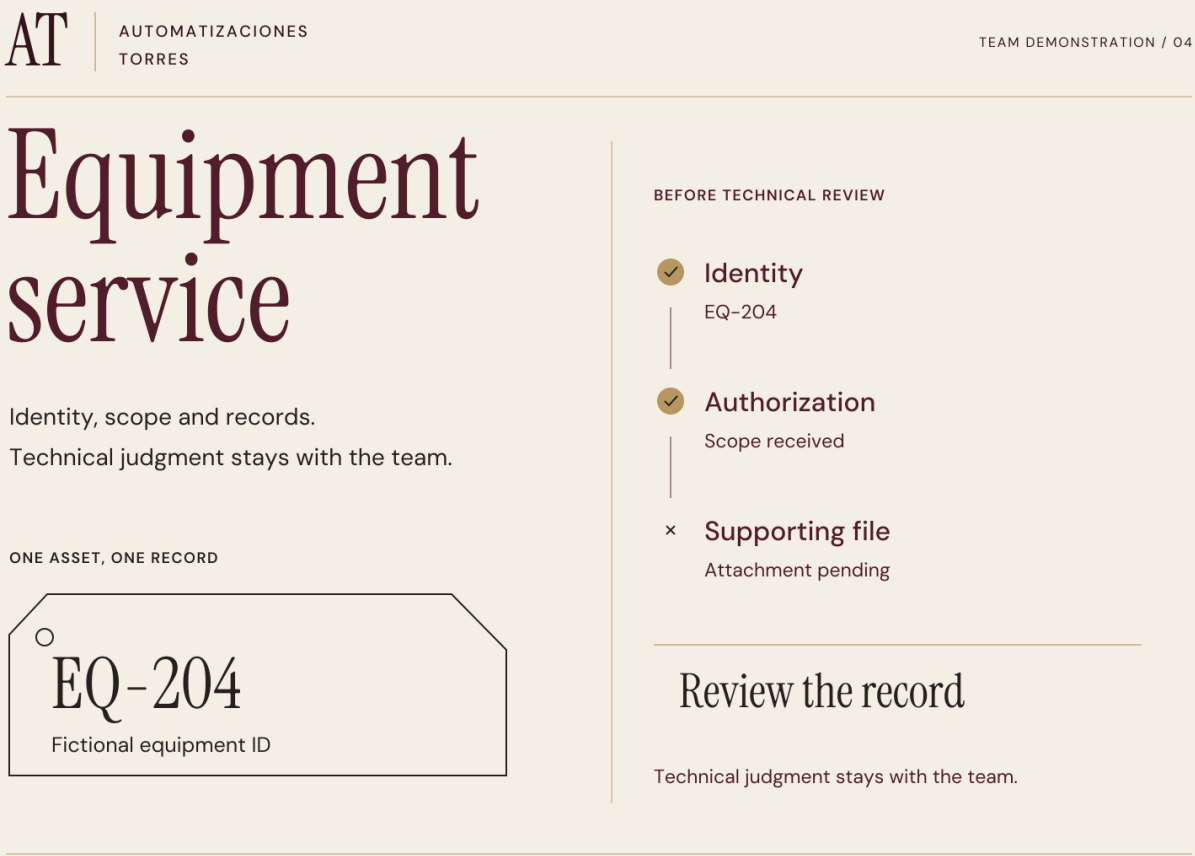

HUMAN CONTROL AND SCOPE

The example makes the rules testable before an operational integration. It contains no live stock and does not independently verify reservation identity. An implementation needs persistent records and concurrency tests. A pilot would review repeated requests, availability differences and orders needing another confirmation.

WHAT WE WOULD MEASURE IN A PILOT

Repeated reservations, availability differences and requests needing additional confirmation.

WORKING DEMONSTRATION - FICTIONAL DATA

THE PROBLEM

A working demonstration with fictional data. When a unit arrives for service, the first difficulty may be identifying the equipment, understanding the authorized work and locating the evidence attached to the request.

WORKFLOW AND OUTPUT

The workflow turns those three conditions into a simple review packet. Each missing item stays explicit, and readiness changes only when all three confirmations are present. The intake owner can explain the outstanding requirement without treating the intervention as approved.

HUMAN CONTROL AND SCOPE

The scope ends at preparing technical review. It does not diagnose faults, determine safety or certify a completed repair. A real pilot would measure identification questions, missing attachments and service-order corrections, without presenting those proposed indicators as an achieved productivity gain.

WHAT WE WOULD MEASURE IN A PILOT

Equipment-identification questions, missing attachments and service-order preparation corrections.

WORKING DEMONSTRATION – FICTIONAL DATA

THE PROBLEM

A working demonstration with fictional data. A reference can match while the received amount differs from the expected amount. The amount can also match without enough evidence to close reconciliation.

WORKFLOW AND OUTPUT

The tool shows the signed difference, validates the amounts and keeps reference matching separate from human review. Invalid inputs remain unknown rather than becoming zero. The next decision depends on evidence and the responsible reviewer.

HUMAN CONTROL AND SCOPE

The example has no bank connection and recognizes no income: recognized income stays at zero even when the fictional records are consistent. An implementation pilot would examine outstanding differences, review time and requests for more evidence. No actual bank movements or financial outcomes are attributed to the demonstration.

WHAT WE WOULD MEASURE IN A PILOT

Outstanding differences, comparison time and decisions requiring additional evidence.

WORKING DEMONSTRATION - FICTIONAL DATA

THE PROBLEM

A working demonstration with fictional data. Follow-up begins before an email: the team needs to distinguish available evidence, a confirmed channel, prior activity and a request not to be contacted again.

WORKFLOW AND OUTPUT

The model keeps those conditions separate. Suppression takes priority, contact history requires a review of the conversation and a simulated first approach needs human approval. An acknowledgment and a meeting keep their own meaning. Neither makes the account a won deal.

HUMAN CONTROL AND SCOPE

Source and mailbox flags are simulation inputs. The example does not call a real verifier, send messages or record a sale. A real operation would measure suitable conversations, progress to proposals and delivery capacity while retaining the reason for each decision.

WHAT WE WOULD MEASURE IN A PILOT

Relevant conversations, progress to meetings or proposals and available delivery capacity.

DOCUMENTED PROPOSAL - OPERATIONS AND FINANCE DESIGN

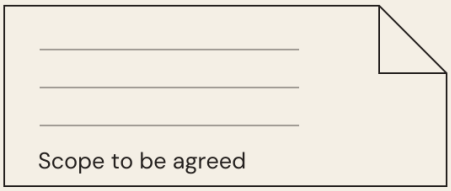

AT | AUTOMATIZACIONES TORRES

SECTOR PROPOSAL / 07

Mining operations

Dispatches, costs and receivables.
Scope to be agreed.

FROM RECORDS TO REVIEW

A proposal, not a deployed operation.

PROPOSED ARCHITECTURE

Dispatch

01 **Tickets**
Quantity and evidence

↓

02 **Costs**
Records to define

↓

03 **Receivables**
Status to confirm

Operator review before moving forward.

Automatizaciones Torres · Proposed design · No production deployment claimed

THE PROBLEM

An operations and finance system proposal for a mining operation. The design follows each transport job from request and dispatch record through advance, unloading and settlement, so the movement and its supporting evidence can be reviewed as one case.

WORKFLOW AND OUTPUT

The workflow brings together costs by operation and equipment, identifies outstanding documents and shows differences before closure. Unique references, deduction rules and possible-duplicate alerts help prepare a reviewable settlement. Assisted document reading produces drafts while the responsible person retains correction, approval and payment authorization.

HUMAN CONTROL AND SCOPE

The analysis produced a documented functional scope with roles, exceptions and criteria for testing the first delivery. My contribution centers on discovery, coordination and scope with the Automatizaciones Torres team. Accounting and payment connections require vendor validation before implementation. The proposal covers finance and operations. Geological and laboratory functions remain outside this scope.

WHAT WE WOULD MEASURE IN A PILOT

Movement traceability, missing evidence, closure time and corrections after review against an agreed baseline.

IMPLEMENTED TEAM PRODUCT – INTERNAL OPERATIONS

Automatizaciones Torres · Schematic view of our internal product · No customer data

THE PROBLEM

An internal product implemented to coordinate the team's commercial operation. It brings research, contact activity and history into one record, helping the owner understand what happened and choose the next step without rebuilding a conversation across several tools.

WORKFLOW AND OUTPUT

Each event retains its source, timestamp and identity. Reconciling the same evidence again preserves existing records. Conflicts are rejected for review and exclusions take priority. The owner can distinguish a draft from a recorded send, a bounce from a reply and a conversation from a proposal or contract.

HUMAN CONTROL AND SCOPE

Email and registry updates use explicit reconciliation, authorized connectors and a readback. The result is a consistent history for reviewing priorities and continuity. Sending remains a separate activity, and this version does not run continuous synchronization. My role connects the operational need with product scope and the team's implementation work.

WHAT WE WOULD MEASURE IN A PILOT

Duplicate records, decisions without evidence, time to reconstruct a conversation and actual progress by stage.

PUBLISHED TEAM PRODUCT – CASE INTAKE

Automatizaciones Torres · Working intake · Fictional example

THE PROBLEM

A published Automatizaciones Torres team product. It turns an initial inquiry into a case the team can review. Visitors explain what happens, where information arrives, the output they need and the decision a person must continue making.

WORKFLOW AND OUTPUT

The bilingual flow lets visitors review their context before sharing it with consent. The server validates fields and files, records one intake per operation and provides a private receipt to recover its status. An optional sample stays attached to the case for authorized team review.

HUMAN CONTROL AND SCOPE

The result is a contextual record that supports continuity when agreeing scope, deliverables and a proposal. My role is to understand the workflow and define that first delivery with the Automatizaciones Torres team. Email notifications, mailbox verification and meeting booking remain a pending integration stage, separate from the intake already saved.

WHAT WE WOULD MEASURE IN A PILOT

Form completion, quality of received context, cases needing clarification and time to review.

AT | AUTOMATIZACIONES TORRES

From one workflow to a first working delivery.

01 Understand one case

We follow a real request, its supporting records and the next owner. We define the entry point and the output the team needs.

02 Define decisions and exceptions

We identify rules, missing information and what a person must approve. Access and integrations are validated before being promised.

03 Build a working part

We agree a first complete part with acceptance criteria and outputs the team can inspect. Documentation accompanies the delivery.

04 Measure the complete effort

We compare preparation, review, corrections and exceptions against an agreed baseline. Improvement is tested with data from that operation.

Jair coordinates discovery, analysis and scope. The Automatizaciones Torres team delivers implementation. Scope, access, price and timing are agreed before work begins.
